### BASF Plant Science

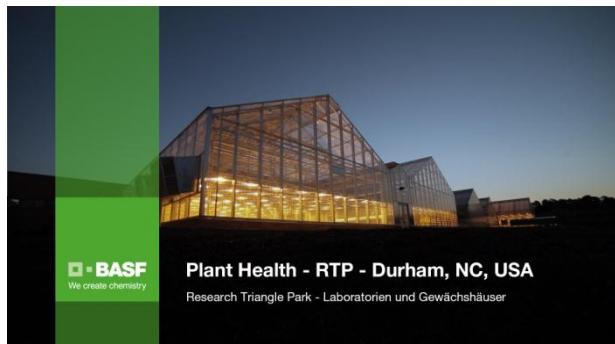

Research Triangle Park (RTP), Durham, North Carolina, USA

**Die BASF Plant Science ist einer der weltweit führenden Anbieter von Pflanzenbiotechnologie für die Landwirtschaft. Unser Hauptsitz am Standort Research Triangle Park bei Raleigh, North Carolina, sichert uns die Nähe zu unseren Hauptmärkten in Nord- und Südamerika.**

Mit unserem globalen Netzwerk von Forschungsstandorten in den USA, in Kanada, Belgien und Deutschland unterstützen wir Landwirte darin, die wachsende Nachfrage nach verbesserter landwirtschaftlicher Produktivität sowie gesünderer Ernährung zu decken. Dafür investiert die BASF jährlich mehr als 150 Millionen €.

#### (01) Laboratorien und Gewächshäuser – Research Triangle Park (RTP)

25.10.2013; 05:34; A1/A2: Atmo; FullHD

**Am BASF-Standort RTP arbeiten rund 950 Mitarbeiter auf einer Fläche von ca. 44.500 m<sup>2</sup>. RTP dient als Zentrale für die Aktivitäten des Unternehmensbereichs Crop Protection der BASF in Nordamerika und als weltweite Zentrale für den Geschäftsbereich Plant Science. Seit der Gründung des Standorts im Jahr 1986 ist die BASF ein bedeutender Akteur der landwirtschaftlichen Industrie North Carolinas.**

BASF Plant Science ist einer der weltweit führenden Anbieter von Pflanzenbiotechnologie-Lösungen für die Landwirtschaft. Mehr als 950 Mitarbeiter unterstützen Landwirte dabei, die wachsende Nachfrage nach verbesserter landwirtschaftlicher Produktivität sowie gesünderer Ernährung zu decken.

### (02) Gewächshaus 5 – Research Triangle Park (RTP)

25.10.2013; 06:34; A1/A2: Atmo; FullHD

Transgene Sojabohnen sind Teil eines Projekts, das zum Ziel hat, Sojabohnen gegen Schadpilze, wie den Asiatischen Sojabohnenrost, resistent zu machen. Dieser Pilz führt jedes Jahr zu hohen wirtschaftlichen Verlusten in der Landwirtschaft.

Die wissenschaftlichen Mitarbeiter Daniela Loaiza und Andrew Rouse überwachen die Qualität der Pflanzen sowie den Zeitpunkt der Blüteninduktion bei Sojabohnenpflanzen im Gewächshaus. Bis zur Samenernte werden die Pflanzen im Gewächshaus gezüchtet.

### (03) Gewächshaus 7 – Research Triangle Park (RTP)

25.10.2013; 07:14; A1/A2: Atmo; FullHD

**Schadpilze bei Mais führen jedes Jahr zu hohen wirtschaftlichen Verlusten. Die BASF Plant Science entwickelt Pflanzenmerkmale, um Maispflanzen resistent gegenüber verschiedenen Schadpilzen zu machen.**

Im Rahmen des Projekts für pilzresistenten Mais werden im Gewächshaus Spendermaispflanzen gezüchtet. Die Kolben einer nicht-transgenen Maispflanze werden wenige Tage nach der Befruchtung geöffnet, um die Entwicklung der noch unreifen Keimlinge zu prüfen. Diese Keimlinge werden später für die Transformation verwendet.

### (04) Transformationslabor – Research Triangle Park (RTP)

25.10.2013; 06:26; A1/A2: Atmo; FullHD

**Der Research Triangle Park (RTP) in North Carolina (USA) ist eines von sechs BASF-Zentren für Forschung und Entwicklung in Nordamerika. Der RTP verfügt über Labore und Gewächshäuser für verschiedene Forschungs- und Entwicklungsprojekt.**

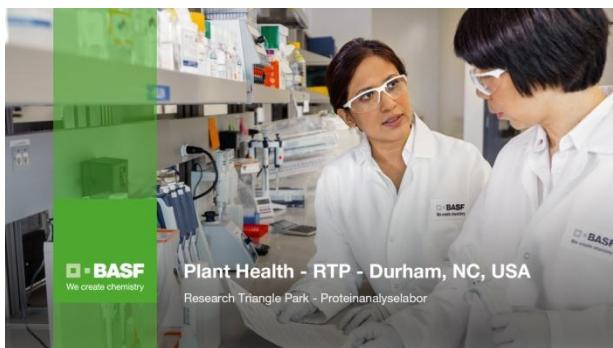

Die leitende wissenschaftliche Mitarbeiterin der Transformationsgruppe, Aparna Sri Vanguri, untersucht junge transgene Maispflanzen. Erfolgreich transformierte Maiszellen können das gewünschte neue Merkmal tragen, zum Beispiel Resistenz gegenüber Schadpilzen oder Herbiziden.

### (05) Proteinanalyselabor – Research Triangle Park (RTP)

25.10.2013; 08:33; A1/A2: Atmo; FullHD

Die Untersuchungen im Proteinanalyselabor unterstützen die Entwicklung und Charakterisierung von Biotechnologie-Traits. Die BASF Plant Science entwickelt Traits, die Pflanzen schadpilzresistenter, herbizidtolerant und ertragreicher machen.

Die leitende Wissenschaftlerin Helen Mu und die wissenschaftliche Mitarbeiterin Wasima Wahid untersuchen die Ergebnisse eines so genannten Assay-Versuchs, der zur Quantifizierung von Proteinen in Pflanzenextrakten durchgeführt wird.

### (06) Chris Kafer – Senior Scientist (Fungal Resistant Corn Research)

25.10.2013; 03:26; A1/A2: O-Ton; FullHD

(Statement ausschließlich auf Englisch)

00:06

*It's becoming increasingly clear that fungal diseases for farmers are becoming a bigger problem. It reduces a yield; it decreases the quality of the grain as well. So we have a multi-step approach and one of the first things that we do is called: gene discovery. And we will find plants that are naturally resistant to the fungi that infect corn and then we will test those in our greenhouse and we will find the underlying genes they give these plants resistance. Then after we discover those genes, we transfer them into corn which will then, we hope, give resistance to these pathogens. After that, after we find genes that work, we're going on what we call our optimization phase of the project where we take combinations of genes. Maybe we manipulate the genes a little bit and then put them back into corn to get a better effect.*

01:06

*Scientifically this project is interesting to work on, because right now they are very few options for corn growers to control these pathogens. Fungicides don't work; there is very limited genetic resistance available out there as well. So this provides a real tremendous opportunity for biotechnology to solve the problem. And we think it is only getting got worse as our climate warms and as our population grows. I think it'll be fascinating to really look at how these pathogens and plants interact and then use that information to design a strategy to help maize resist attack by fungal pathogens.*

01:47

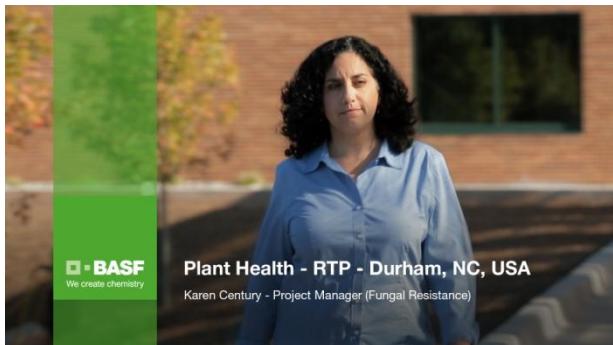

*The fungal resistance corn project is at very beginnings of its gene discovery activities. This means that we're currently screening a lot of different kinds of plants in our greenhouse to trying find these plants that are naturally resistant to pathogens. And we've also begun our process of gene discovery which means that we have identified some genes from our previous work that we're now putting into corn. And in fact we'll have our first genetically modified corn for testing.*

### (07) Karen Century – Project Manager (Fungal Resistance)

25.10.2013; 03:59; A1/A2: O-Ton; FullHD

**(Statement ausschließlich auf Englisch)**

00:06

*Fungal diseases have a tremendous negative impact on corn yield and the fungal diseases that we're focusing on, which are the corn stalk and ear rots, are estimated to cause well over one billion dollars in yield loss every year in the US alone. And these particular diseases have not been well controlled with fungicides or conventional breeding solutions. So they really offer an excellent market opportunity and target for our biotech approach.*

00:37

*BASF plant Science already has significant experience in this field with the launch of our soya-bean fungal resistance project earlier and so we really have developed a great deal of expertise in fungal biology and in engineering disease resistance in plants.*

00:56

*Corn growers suffer truly significant financial hit due to diseases that affect their crops and their yield which means financial impact for them. The diseases that we are focusing on, the stalk and ear rots, are especially important, because they cause a major economic damage in corn crops and because there really are no good solutions for control right now with chemistries or conventional breeding. So our ability to offer growers a solution*

## Sehen, was bewegt:

der BASF TV-Service für TV- und Onlinejournalisten unter  
**tvservice.bASF.com**

*with genetically engineered crops will have a tremendous impact on the corn grower's ability to preserve yield and maintain the best harvest.*

01:38

*BASF plant science is truly a global leader in providing plant biotechnology solutions for agriculture. We support farmers by helping them meet the growing demand for crops with increased yields, increased stress tolerance and better nutrition. And with our truly industry leading platform in gene discovery we've really specialized on discovering and developing complex traits which provide improved yields and just better quality crops, for crops such as corn, soya-bean and rice. And fungal resistance is actually one of BASF plant sciences three strategic pillars. And actually focusing on corn stalk and ear rots for this project is especially important because we're really going to provide a significant benefit to the farmer by filling this gap in a disease management program. And it also really complements our portfolio of chemical solutions for other corn diseases. So it's a really nice fit.*

02:47

*As we go into the future thus going to be even more demand for research in plant science. In this has largely to do with not just that growers needs, but a growing population which is putting a lot of strain on earth resources for producing enough food to feed everyone, for fiber, for feed, for everything. And so I only see the need is getting greater.*

### (08) Stuart Kaplan – Senior Manager (Corn Development)

25.10.2013; 04:15; A1/A2: O-Ton; FullHD

**(Statement ausschließlich auf Englisch)**

00:06

*Plant science in the general sense is to provide enough food, enough feed and enough fiber for growing planet. When I was a young child and looking for something to do as an adult, agriculture just obviously seemed obviously to me, I'd like to say, I grew up on a farm, I always had a fascination with plants and so I grabbed it in that direction and I learned over time as a youngster, that for human beings to survive, we all depend on plants: either through direct consumption of plant tissue or the consumption of meat products produced from animals that can turn consume plants. It's a fundamental biology of human existence quite honestly, so plant science will be with us as long as we are here.*

00:54

*Well we're doing a number of different things. We are looking at ways that we can infect corn plants artificially with a fungal inoculation that we have isolated from mother nature and so looking at ways to inoculate thousands of plants very efficiently at very precise times and then subsequently come back harvest those plants and evaluate the level of fungal infection. Because we are dealing with numbers that are very, very large, efficiency and safety are of paramount importance along with accuracy. So we had, we are looking at methods to infect, we are looking at methods to harvest, we are looking at methods to evaluate, we are also looking for the best pass and the best*

## Sehen, was bewegt:

der BASF TV-Service für TV- und Onlinejournalisten unter  
**tvservice.bASF.com**

*varieties of corn, if you will that, express these traits in useful way. So that's something else that we are doing here, we are doing this in multiple locations in the United States.*

01:50

*How much fungal resistance is necessary for there to be a product? And so we need to have methods which we're working on they will enable us to quantify, to measure how much resistance there is to a fungal infection in a corn plant. We don't have a methods thoroughly worked out yet, but we're working on any number of different methods and I'm comfort to work on a settle on a number of methods that will be safe, efficient and accurate. That's what our primary goal is: to get the safe, efficient and accurate methods that we can use in assessing fungal resistance in corn.*

02:23

*Well the biggest challenges we face in looking at fungal resistance: normally if you're looking at a response, at a genetic response in corn plant to something that we think we will increase yield, you're just looking really at corn plant, the corn varieties if you will. But here we're looking at an interaction between our corn plants and fungi and these are two very different organisms and the ability of a fungus to invade and infect and cause damage in a corn plant is a functional environment.*

### (09) Sheila Bhattacharya – Lab Manager (Plant Management)

25.10.2013; 02:01; A1/A2: O-Ton; FullHD

**(Statement ausschließlich auf Englisch)**

00:06

*I'm the lab manager for the plant management which is actually the greenhouse manager position; but I also manage all the research projects for transgenic and non-transgenic crop pipeline for soya-beans and corn. I manage almost eighty research projects on in all over 70.000 square meters in the greenhouses that we have at BASF at our R&D location here.*

00:34

*This greenhouse has been built by Rough Brothers, which is a good research greenhouse company. So I worked very closely with them to add some features in the greenhouses that we had before to make it a better environment for growing the current crops that we have and for future. And also from a stewardship point of view this is designed from separating the transgenic and non-transgenic... We are going to add more efficiency components into these greenhouses pretty soon by end of this year. So we will have more automation and irrigation and fertilizer capabilities.*

## Sehen, was bewegt:

der BASF TV-Service für TV- und Onlinejournalisten unter  
**tvservice.bASF.com**

01:21

*So I was a big part in designing, too the added features in this greenhouse 7, for particularly for growing corn and also this can be used for growing other crops as well for future research needs. So it has got a lot of structural changes like an adjustable light system, we have a better cooling system, better UV benefiting panels in this greenhouse. So we can have a very close environment compare to the outside for growing plants.*
